History 0–1 hour after bite

A man was bitten on a toe on his right foot while in his yard. He was moving lawn furniture when he felt a sharp prick on the third toe of his right foot. When he looked down, he noticed a copperhead snake slithering away. He then decided to drive himself to the emergency department at his local hospital.
Presentation at hospital — 1–4 hours after the bite

- Patient had no significant medical history or known allergies
- Patient appeared well, complained of local pain around bite site

**Local effects:** Two puncture marks noted on third toe of right foot; no significant edema of affected toe; tenderness noted around bite site

**Vital signs:** Blood pressure 115/80 mm Hg, heart rate 74/min, respiratory rate 17/min

**Lab values:** Prothrombin time 11.5 seconds, INR 1.1, fibrinogen 250 mg/dL, platelets 191,000 /mm$^3$

- Patient not given antivenom because swelling “did not cross a major joint”
- Foot elevated
- Observed for 4 hours and discharged from hospital and sent home

---

**Day 2: Patient seeks additional medical attention**

- Patient experienced continued pain and swelling at the bite site; visited his primary care physician
- Primary care physician prescribed an antibiotic

---

**Day 3: Symptoms remain unresolved and worsen**

- Experienced continued pain
- Toe has swelled significantly, developed hemorrhagic bulla, discoloration (purple)
- Primary care physician prescribed medication for pain and inflammation

---

**Day 4: Medical expert consulted**

- Patient continued to experience swelling at the bite site and pain; called his primary physician who referred him to the local snakebite expert
- Snakebite expert recommended patient visit the local wound care clinic
Day 7–15: Medical expert consulted

- Hemorrhagic bulla was drained from affected toe
- Patient experienced intense hypersensitivity and extreme pain in toe
- Wound care clinic drained and debrided toe
- **Patient experienced difficulty walking**
- **Patient unable to attend work during this time**

Days 15–30: Continued wound care visits

Post Day 30: Additional treatment modalities considered

- Continued visiting a wound care specialist
- Skin graft considered for affected toe, however, not performed
- Significant pain and sensitivity continued
- Toenail turned purple and black before falling off (6 weeks post-envenomation)

Recovery 4 months–3 years

- Pain medication discontinued 60 days post envenomation
- Wound healed 4 months after bite
- Numbness and tingling at bite site continued up to 12 months post-envenomation
- Scarring and toenail deformity persists after 3 years

Indication

CroFab® Crotalidae Polyvalent Immune Fab (Ovine) is a sheep-derived antivenin indicated for the management of adult and pediatric patients with North American crotalid envenomation. The term crotalid is used to describe the Crotalinae subfamily (formerly known as Crotalidae) of venomous snakes which includes rattlesnakes, copperheads and cottonmouths/water moccasins.

Please see Important Safety Information on back cover and enclosed full Prescribing Information.
Key considerations

- **Insufficient duration of observation for a snakebite patient¹**
  - Patients should be observed for at least 8 hours prior to discharge to determine if a bite is a dry bite or an envenomation

- **Decision not to treat what appeared to be a mild snakebite with antivenom may have contributed to progression and severity of the envenomation**
  - After initially appearing as a mild envenomation, the envenomation continued to progress with unresolved severe pain and affected activities of daily living

- **Consider location of bite in decision to treat**
  - Envenomation in digits and the hand can result in amplified local tissue damage and adverse long-term outcomes²

- **Consult an expert if symptoms of envenomation persist**
  - Call your local poison control center at 1-800-222-1222 if an expert is needed to consult for snakebite treatment

**IMPORTANT SAFETY INFORMATION**

**CONTRAINDICATIONS**

Do not administer CroFab® to patients with a known history of hypersensitivity to any of its components, or to papaya or papain unless the benefits outweigh the risks and appropriate management for anaphylactic reactions is readily available.

**WARNINGS AND PRECAUTIONS**

**Coagulopathy**: In clinical trials, recurrent coagulopathy (the return of a coagulation abnormality after it has been successfully treated with antivenin), characterized by decreased fibrinogen, decreased platelets, and elevated prothrombin time, occurred in approximately half of the patients studied; one patient required re-hospitalization and additional antivenin administration. Recurrent coagulopathy may persist for 1 to 2 weeks or more. Patients who experience coagulopathy due to snakebite should be monitored for recurrent coagulopathy for up to 1 week or longer. During this period, the physician should carefully assess the need for re-treatment with CroFab® and use of any type of anticoagulant or anti-platelet drug.

**Hypersensitivity Reactions**: Severe hypersensitivity reactions may occur with CroFab®. In case of acute hypersensitivity reactions, including anaphylaxis and anaphylactoid reactions, discontinue infusion and institute appropriate emergency treatment. Patients allergic to papain, chymopapain, other papaya extracts, or the pineapple enzyme bromelain may also have an allergic reaction to CroFab®. Follow-up all patients for signs and symptoms of delayed allergic reactions or serum sickness (e.g., rash, fever, myalgia, arthralgia).

**ADVERSE REACTIONS**

The most common adverse reactions (incidence ≥ 5% of subjects) reported in the clinical studies were urticaria, rash, nausea, pruritus and back pain. Adverse reactions involving the skin and appendages (primarily rash, urticaria, and pruritus) were reported in 12 of the 42 patients. Two patients had a severe allergic reaction (severe hives and a severe rash and pruritus) following treatment and one patient discontinued CroFab® due to an allergic reaction. Recurrent coagulopathy due to envenomation and requiring additional treatment may occur.

**Please see enclosed full Prescribing Information.**

When envenomation strikes, strike back with CroFab®. [www.crofab.com](http://www.crofab.com)
History

0–20 minutes after bite

A child playing at summer day camp was bitten on the right leg by a rattlesnake (identified by another camper).

Within 20 minutes of the bite, the patient had arrived at the nearest hospital stocking antivenom.

Based on an actual case study; details changed to preserve patient confidentiality.

Individual results may vary.

These educational patient case studies are brought to you by BTG International Inc.

The purpose of these case studies is to educate healthcare professionals about the potential benefits, potential risks, and potential uses of BTG products.

Photo shown above is not an actual patient.

Please see Important Safety Information on back cover and enclosed full Prescribing Information.
**Presentation at hospital**  
- 20 minutes–1 hour

- Patient had no significant medical history or known allergies to medications or food
- General assessment: patient appeared well, mildly anxious, able to answer questions
- No evidence of neurotoxicity or bleeding

**Local effects:** Raised, erythematous, tender area around puncture; pain rating: 8 out of 10. Calf circumference: 28 cm (23 cm for left leg), with swelling extending almost to popliteal fossa

**Vital signs:** Blood pressure 114/80 mm Hg, heart rate 118/min, respiratory rate 28/min

**Lab values:** Prothrombin time 15.8 seconds, INR 1.3, fibrinogen 130 mg/dL, platelets 90,000/mm³

- Right leg elevated and immobilized
- Medical staff marked the leading edge of the swollen, tender area of the leg on initial examination and reexamined the area every 15-30 minutes to assess progression of the local tissue effects
- Patient given normal saline for IV fluid hydration and IV fentanyl for pain as needed

---

**Start of treatment**  
- 1–2 hours

- CroFab® administered immediately, following the treatment algorithm

  - **Initial dose:** 6 vials via IV infusion over 1 hour, monitoring the patient closely for any allergic reactions

---

**Achieving initial control**  
- 2 hours

**Local effects:** Leading edge of swollen area and limb circumference unchanged from previous assessment

**Vital signs:** Within normal limits

**Lab values:** Prothrombin time 11.5 seconds, INR 1.1, fibrinogen 180 mg/dL, platelets 192,000/mm³

- Initial control achieved 2 hours post envenomation

---

INR=international normalized ratio.
Continuing control — 3–21 hours

- After initial control was achieved, dosing was continued to minimize the risk of recurrent or delayed venom effects
  - **2 additional vials of CroFab® administered at 6, 12, and 18 hours after initial control was achieved**
- No progression of envenomation overnight

CroFab® contains mercury in the form of ethyl mercury from thimerosal. Although there are limited toxicology data on ethyl mercury, high dose and acute exposures to methyl mercury have been associated with neurological and renal toxicities. Developing fetuses and very young children are most susceptible and therefore, at greater risk.

Outcome — 24–120 hours

- Follow-up vital signs and lab values 24 hours after arrival at the hospital were within normal limits
- Patient improved and was discharged to home on Day 2
- Patient’s family was instructed to:
  - Keep her leg elevated and immobilized
  - Contact her pediatrician immediately if signs of recurrent coagulopathy or delayed allergic reaction occur
  - Avoid dental work for 2 weeks
- Patient’s lab values were normal at follow-up visit with pediatrician on Day 3 after snakebite. She returned to camp on Day 5

Indication

CroFab® Crotalidae Polyvalent Immune Fab (Ovine) is a sheep-derived antivenin indicated for the management of adult and pediatric patients with North American crotalid envenomation. The term crotalid is used to describe the Crotalinae subfamily (formerly known as Crotalidae) of venomous snakes which includes rattlesnakes, copperheads and cottonmouths/water moccasins.

Key considerations

- **Appropriate starting dose was administered without delay**
  - Initial control was quickly achieved as local effects were halted

- **Considered local, systemic, and hematologic effects when monitoring and evaluating patient**
  - Hospital staff continued to monitor for all 3 types of envenomation effects until discharge

- **Recommended maintenance dosing administered**
  - Continue CroFab® dosing after initial control to help prevent recurrent venom effects

- **Stocked antivenom in accordance with expert consensus stocking guidelines**
  - Patient needs were addressed because hospital stocked sufficient amount of antivenom

---

**IMPORTANT SAFETY INFORMATION**

**CONTRAINDICATIONS**

Do not administer CroFab® to patients with a known history of hypersensitivity to any of its components, or to papaya or papain unless the benefits outweigh the risks and appropriate management for anaphylactic reactions is readily available.

**WARNINGS AND PRECAUTIONS**

**Coagulopathy**: In clinical trials, recurrent coagulopathy (the return of a coagulation abnormality after it has been successfully treated with antivenin), characterized by decreased fibrinogen, decreased platelets, and elevated prothrombin time, occurred in approximately half of the patients studied; one patient required re-hospitalization and additional antivenin administration. Recurrent coagulopathy may persist for 1 to 2 weeks or more. Patients who experience coagulopathy due to snakebite should be monitored for recurrent coagulopathy for up to 1 week or longer. During this period, the physician should carefully assess the need for re-treatment with CroFab® and use of any type of anticoagulant or anti-platelet drug.

**Hypersensitivity Reactions**: Severe hypersensitivity reactions may occur with CroFab®. In case of acute hypersensitivity reactions, including anaphylaxis and anaphylactoid reactions, discontinue infusion and institute appropriate emergency treatment. Patients allergic to papain, chymopapain, other papaya extracts, or the pineapple enzyme bromelain may also have an allergic reaction to CroFab®. Follow-up all patients for signs and symptoms of delayed allergic reactions or serum sickness (e.g., rash, fever, myalgia, arthralgia).

**ADVERSE REACTIONS**

The most common adverse reactions (incidence ≥ 5% of subjects) reported in the clinical studies were urticaria, rash, nausea, pruritus and back pain. Adverse reactions involving the skin and appendages (primarily rash, urticaria, and pruritus) were reported in 12 of the 42 patients. Two patients had a severe allergic reaction (severe hives and a severe rash and pruritus) following treatment and one patient discontinued CroFab® due to an allergic reaction. Recurrent coagulopathy due to envenomation and requiring additional treatment may occur.

Please see enclosed full Prescribing Information.

When envenomation strikes, strike back with CroFab®. [www.crofab.com](http://www.crofab.com)
A woman was bitten on her right index finger while in her yard. She was doing yardwork with her parents when she felt a pinprick on her finger. A few hours later, she noticed that her hand had started to swell and she was experiencing pain. Her parents decided to call 911 after noticing two puncture marks on her right index finger and then brought her to the emergency department.
Presentation at hospital — 4–7 hours after the bite

- Patient had no significant medical history or known allergies to medications or food
- General assessment: Patient having issues with pain control, able to answer questions, appeared mildly anxious
- Puncture marks on right index finger, pain and swelling halfway up the forearm
- **Upon initial evaluation, facility unsure of species and questioned whether to treat with antivenom**

**Local effects:** Edema noted up to forearm; no evidence of bleeding; pain rating 8 out of 10
**Vital signs:** Blood Pressure 122/76 mm Hg, heart rate 84/min, respiratory rate 20/min
**Lab values:** Prothrombin time 11 seconds, INR 1.1, fibrinogen 314 mg/dL, platelets 176,000/mm³

- Hospital staff noticed that swelling had progressed towards the elbow since admission to the emergency department
- **No toxicologist on staff at hospital; called their local poison control center to speak with their on-call toxicologist**
- **Toxicologist suspected a pit viper envenomation and recommended administration of antivenom due to progression of swelling**

Start of treatment — 7–9 hours

- Based off the toxicologist consult, hospital staff decided to administer CroFab® according to the treatment algorithm
  - Initial dose: 6 vials via IV infusion over 1 hour, monitoring patient closely for any allergic reactions
- After 6 vial initial dose, monitored for swelling
- Continued progression of swelling and pain noted at Hour 8
- Initial control not achieved due to continued progression of swelling
- Hospital staff consulted local poison control center again and was advised to give an additional 4 to 6 vials to gain initial control
- **Additional 4 vials of CroFab® administered ~1 hour after end of first infusion according to the toxicologist recommendation and treatment algorithm**

INR = international normalized ratio.
**Achieving initial control — 9–10 hours**

- Observed patient, swelling no longer progressing after second dose of CroFab®
- Lab values and vital signs within normal limits
- Initial control achieved at 10 hours post envenomation

**Continuing control — 10–41 hours**

- Administered scheduled maintenance dosing regimen of 2 vials of CroFab® at 6, 12, and 18 hours after initial control was achieved

- Discharge criteria:
  - Swelling had diminished; still minimal swelling surrounding bite site
  - Vital signs and lab values were within normal limits
  - Improved range of motion
  - Pain had resolved
- Patient discharged 12 hours after last dose of CroFab®. Instructions included to contact physician immediately if signs of recurrent coagulopathy or delayed allergic reaction occur

**Outcome — 10 days–14 days**

- Outpatient follow up
  - Patient doing well
  - No visible edema
- 2nd follow up
  - No further treatment needed

**Indication**

CroFab® Crotalidae Polyvalent Immune Fab (Ovine) is a sheep-derived antivenin indicated for the management of adult and pediatric patients with North American crotalid envenomation. When envenomation strikes, strike back with CroFab®. [www.crofab.com](http://www.crofab.com)
A man was bitten on his left calf by a rattlesnake while hiking with 2 friends. He heard a hiss in the brush and felt searing pain as the snake, estimated at 6’ to 8’ long, bit his left leg. He developed nausea, vomiting, and left leg swelling. After his friends dialed 911, they helped him walk 1 hour to reach an emergency medical technician, who elevated and immobilized his leg, then transported him to an open field, from which a medevac helicopter brought him to a major medical center.

Based on an actual case study; details changed to preserve patient confidentiality.

Individual results may vary.

These educational patient case studies are brought to you by BTG International Inc.

The purpose of these case studies is to educate healthcare professionals about the potential benefits, potential risks, and potential uses of BTG products.

Photo shown above is not an actual patient.

Please see Important Safety Information on back cover and enclosed full Prescribing Information.
Presentation at hospital — 3–4 hours after the bite

- Patient had no significant medical history or known allergies to medications or food
- General assessment: patient in severe pain, anxious, able to answer questions; complained of dizziness and metallic taste in mouth
- Left leg showed blood oozing from bite site, fasciculations, and myokymia

**Local effects:** Left leg erythematous, swollen, warm, and tender to touch, with ecchymosis and skin blisters surrounding the bite site; bleeding from the bite site; pain rating 9 out of 10; calf circumference: 46 cm (40 cm for right leg), with swelling extending to popliteal fossa

**Vital signs:** Blood pressure 92/64 mm Hg, heart rate 136/min, respiratory rate 24/min

**Lab values:** Prothrombin time 17.9 seconds, INR 2.4, fibrinogen 61 mg/dL, platelets 35,000/mm³

- Medical staff marked leading edge of erythematous, swollen area of leg on initial examination and reexamined area every 15-30 minutes to assess progression of envenomation
- Patient given normal saline for IV fluid hydration and morphine IV for pain as part of initial therapy
- Medical staff recognized that the patient was experiencing a severe envenomation. Severe envenomations are unpredictable and may lead to extreme outcomes

**Start of treatment** — 4–6 hours

- CroFab® administered according to the treatment algorithm
  - **Initial dose:** 12 vials via IV infusion over 1 hour, monitoring the patient closely for any allergic reactions
  - Progression of erythema, swelling, pain, and tenderness noted at hour 6, with formation of skin blisters
- Initial control not achieved. Decision made to administer another dose of CroFab® according to the treatment algorithm
- **Additional 6 vials of CroFab® administered ~1 hour after end of first infusion**

**Achieving initial control** — 7 hours

- **Stabilization of local, systemic, and hematologic venom effects achieved within 7 hours after bite**

  **Local effects:** Erythema, swelling, and tenderness began to resolve
  **Vital signs:** Blood pressure 126/78 mm Hg, heart rate 88/min, respiratory rate 16/min
  **Lab values:** Prothrombin time 13.6 seconds, INR 1.1, fibrinogen 148 mg/dL, platelets 135,000/mm³

INR = international normalized ratio.
Continuing control – 15 hours–Day 4

- Patient transferred from ER to ICU with recommendation for continued dosing of 2 vials of CroFab® at 6, 12, and 18 hours after initial control to minimize the risk of recurrent or delayed venom effect
- Deterioration of patient’s clinical condition 5 hours after ICU admission: progressive worsening of pain, tenderness, swelling, ecchymosis, blister formation, and oozing of dark blood from bite site
- At 6 hours after ICU admission, staff prepared to administer next recommended CroFab® dose, but they discovered that hospital had exhausted its supply of 18 vials, causing a 12-hour delay in CroFab® treatment
- During this time, patient’s clinical course continued to deteriorate, with progressive local tissue effects, including severe myonecrosis adjacent to bite
- Due to progressive myonecrosis and neurovascular compromise of the lower leg, a below-knee amputation was performed without incident on Day 4 after snakebite

Outcome – Days 5-9

- Patient’s post-op recovery was unremarkable
- Patient discharged on Day 8 post-op to a rehabilitation facility for physical therapy and amputee training
- Patient recovered slowly, with more additional surgeries scheduled to optimize limb function

Indication

CroFab® Crotalidae Polyvalent Immune Fab (Ovine) is a sheep-derived antivenin indicated for the management of adult and pediatric patients with North American crotalid envenomation. The term crotalid is used to describe the Crotalinae subfamily (formerly known as Crotalidae) of venomous snakes which includes rattlesnakes, copperheads and cottonmouths/water moccasins.

IMPORTANT SAFETY INFORMATION

CONTRAINDICATIONS
Do not administer CroFab® to patients with a known history of hypersensitivity to any of its components, or to papaya or papain unless the benefits outweigh the risks and appropriate management for anaphylactic reactions is readily available.

WARNINGS AND PRECAUTIONS

Coagulopathy: In clinical trials, recurrent coagulopathy (the return of a coagulation abnormality after it has been successfully treated with antivenin), characterized by decreased fibrinogen, decreased platelets, and elevated prothrombin time, occurred in approximately half of the patients studied; one patient required re-hospitalization and additional antivenin administration. Recurrent coagulopathy may persist for 1 to 2 weeks or more. Patients who experience coagulopathy due to snakebite should be monitored for recurrent coagulopathy for up to 1 week or longer. During this period, the physician should carefully assess the need for re-treatment with CroFab® and use of any type of anticoagulant or anti-platelet drug.

Hypersensitivity Reactions: Severe hypersensitivity reactions may occur with CroFab®. In case of acute hypersensitivity reactions, including anaphylaxis and anaphylactoid reactions, discontinue infusion and institute appropriate emergency treatment. Patients allergic to papain, chymopapain, other papaya extracts, or the pineapple enzyme bromelain may also have an allergic reaction to CroFab®. Follow-up all patients for signs and symptoms of delayed allergic reactions or serum sickness (e.g., rash, fever, myalgia, arthralgia).

ADVERSE REACTIONS
The most common adverse reactions (incidence ≥ 5% of subjects) reported in the clinical studies were urticaria, rash, nausea, pruritus and back pain. Adverse reactions involving the skin and appendages (primarily rash, urticaria, and pruritus) were reported in 12 of the 42 patients. Two patients had a severe allergic reaction (severe hives and a severe rash and pruritus) following treatment and one patient discontinued CroFab® due to an allergic reaction. Recurrent coagulopathy due to envenomation and requiring additional treatment may occur.

Please see enclosed full Prescribing Information.

When envenomation strikes, strike back with CroFab®. www.crofab.com

Key considerations

- Considered local, systemic, and hematologic effects of envenomation when monitoring and evaluating patient
- Aggressive dosing strategy helped achieve initial control
  - Continuous monitoring of envenomation symptoms is critical to assessing if initial control has been achieved
- Stock enough CroFab® to complete treatment and prepare a plan for how to obtain CroFab® quickly for additional doses
  - 18 vials were needed to achieve initial control, leaving no vials for scheduled maintenance dosing
HIGHLIGHTS OF PRESCRIBING INFORMATION
These highlights do not include all the information needed to use CROFAB safely and effectively. See full prescribing information for CROFAB.

CROFAB® crotalidae polyvalent immune fab (ovine)
Lyophilized Powder for Solution for Intravenous Injection
Initial U.S. Approval: 2000

-------------------INDICATIONS AND USAGE-------------------
CROFAB is a sheep-derived antivenin indicated for the management of adult and pediatric patients with North American crotalid envenomation. (1)

-------------------dosage and administration-------------------
For intravenous use only
• Initiate administration as soon as possible after snake bite in patients who develop signs of envenomation (e.g. local injury, coagulation abnormality or systemic signs of envenomation)
• Dose: (2.1)
  o Recommended initial dose is between 4 and 6 vials
  o Observe patient for up to one hour after the initial dose and give an additional 4-6 vial dose as needed to gain initial control of envenomation
  o After initial control is established, administer additional 2-vial doses every 6 hours for 18 hours (total of 3 doses)
• Administration: (2.2)
  o Reconstitute each vial of CROFAB with 18 mL of 0.9% Sodium Chloride and mix by continuous manual inversion until no solid material is visible in the vial
  o Do not shake
  o Further dilute the entire dose with 0.9% Sodium Chloride to a total volume of 250 mL
  o Infuse each dose intravenously over at least 1 hour

-------------------Dosage Forms and Strengths-------------------
CROFAB is available as lyophilized powder. Each vial contains up to 1 gram of total protein, a maximum of 0.03 mg of mercury and not less than the indicated number of mouse LD₅₀ neutralizing units:

<table>
<thead>
<tr>
<th>Snake Species Used for Antivenin Component</th>
<th>Minimum mouse LD₅₀ Units per vial</th>
</tr>
</thead>
<tbody>
<tr>
<td>C. atrox (Western Diamondback rattlesnake)</td>
<td>1270</td>
</tr>
<tr>
<td>C. adamanteus (Eastern Diamondback rattlesnake)</td>
<td>420</td>
</tr>
<tr>
<td>C. scutulatus (Mojave rattlesnake)</td>
<td>5570</td>
</tr>
<tr>
<td>A. piscivorus (Cottonmouth or Water Moccasin)</td>
<td>780</td>
</tr>
</tbody>
</table>

-------------------CONTRAINDICATIONS-------------------
Do not administer CROFAB to patients with a known history of hypersensitivity to any of its components, or to papaya or papain unless the benefits outweigh the risks and appropriate management for anaphylactic reactions is readily available. (4)

-------------------WARNINGS AND PRECAUTIONS-------------------
• Monitor patients for recurrent coagulopathy for one week or longer following treatment of the bite (5.1)
• Hypersensitivity reactions, including anaphylaxis, may occur
• Patients allergic to papain, chymopapain, papaya extracts, or bromelain (pineapple enzyme), may react to CROFAB (5.2)
• Treatment with the maximum dose of CROFAB used in clinical trials (18 vials) will deliver up to 0.6 mg of ethyl mercury (thimerosal) to a patient (5.3)

-------------------ADVERSE REACTIONS-------------------
Most common adverse reactions (incidence ≥5% of subjects): urticaria, rash, nausea, pruritus and back pain. Allergic reaction (severe hives and a severe rash and pruritus) has occurred following treatment. Recurrent coagulopathy due to envenomation and requiring additional treatment may occur. (6.1)

To report SUSPECTED ADVERSE REACTIONS, contact 1-877-377-3784 or FDA at 1-800-FDA-1088 or www.fda.gov/medwatch.

CROFAB® CROTALIDAE POLYVALENT IMMUNE FAB (OVINE)

FULL PRESCRIBING INFORMATION

1 INDICATIONS AND USAGE

CROFAB is indicated for the management of adult and pediatric patients with North American crotalid envenomation. The term crotalid is used to describe the Crotalinae subfamily (formerly known as Crotalidae) of venomous snakes which includes rattlesnakes, copperheads and cottonmouths/water moccasins.

2 DOSAGE AND ADMINISTRATION

For intravenous use only

2.1 Dosage

- Administer CROFAB as soon as possible in patients who develop any signs of envenomation (e.g., local injury, coagulation abnormality or systemic signs of envenomation) to prevent clinical deterioration. CROFAB was shown in clinical studies to be effective when given within 6 hours of snakebite.

- Antivenin dosage requirements are contingent upon an individual patient’s response. Based on clinical experience with CROFAB, the recommended initial dose is 4 to 6 vials; however, the starting dose may vary from a minimum of 4 vials to a maximum of 12 vials based on clinical judgment and severity of envenomation [3].

- Observe the patient for up to 1 hour following completion of the first dose to determine if initial control of envenomation has been achieved. Initial control is achieved when local signs of envenomation are arrested (leading edge of local injury is not progressing), systemic symptoms are resolved and coagulation parameters have normalized or are trending toward normal. If initial control is not achieved by the first dose, an additional dose of 4 to 6 vials should be administered repeatedly until initial control of the envenomation syndrome has been achieved.

- Once initial control has been achieved, additional 2-vial doses of CROFAB every 6 hours for up to 18 hours (3 doses) are recommended. Optimal dosing following the 18-hour scheduled dose of CROFAB has not been determined. Additional 2-vial doses may be administered as deemed necessary by the treating physician, based on the patient’s clinical course.

- Infusion reactions, such as fever, low back pain, wheezing and nausea, may be related to the rate of infusion and can be controlled by decreasing the rate of administration of the solution [12]. Poison control centers are a helpful resource for individual treatment advice.

2.2 Preparation and Administration

- Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration, whenever solution and container permit.

- Reconstitute each vial of CROFAB with 18 mL of 0.9% Sodium Chloride (diluent not included) and mix by continuous manual inversion until no solid material is visible in the vial. Do not shake. Further dilute the contents of all of the reconstituted vials to a total volume of 250 mL with 0.9% Sodium Chloride and mix by gently swirling.

- Use the reconstituted and diluted product within 4 hours.

- Infuse the dose intravenously over 60 minutes. However, the infusion should proceed slowly over the first 10 minutes at a 25-50 mL/hour rate with careful observation for any allergic reaction. If no such reaction occurs, the infusion rate may be increased to the full 250 mL/hour rate until completion. Close patient monitoring is necessary.

3 DOSAGE FORMS AND STRENGTHS

CROFAB is available as a sterile, nonpyrogenic, purified, lyophilized powder. Each vial contains up to 1 gram of total protein, a maximum of 0.03 mg of mercury and not less than the indicated number of mouse LD$_{50}$ neutralizing units*:

<table>
<thead>
<tr>
<th>Snake Species Used for Antivenin Component</th>
<th>Minimum mouse LD$_{50}$ Units per vial</th>
</tr>
</thead>
<tbody>

<td>C. scutulatus (Mojave rattlesnake)</td>
<td>5570</td>
</tr>
<tr>
<td>A. piscivorus (Cottonmouth or Water Moccasin)</td>
<td>780</td>
</tr>
</tbody>
</table>
As of 2008, the potency assay has been optimized for a new strain of mice, which has resulted in changes to the minimum mouse LD$_{50}$ neutralizing units. These changes do not reflect any change in product potency, but only a different biological response of the mouse strain to the venom.

4 CONTRAINDICATIONS

Do not administer CROFAB to patients with a known history of hypersensitivity to papaya or papain unless the benefits outweigh the risks and appropriate management for anaphylactic reactions is readily available.

5 WARNINGS AND PRECAUTIONS

5.1 Coagulopathy

Coagulopathy is a complication noted in many victims of crotalid envenomation that arises due to the ability of the snake venom to interfere with the blood coagulation cascade [5, 9, 10], and is seen more frequently in severely envenomated patients.

In clinical trials with CROFAB, recurrent coagulopathy (the return of a coagulation abnormality after it has been successfully treated with antivenin), characterized by decreased fibrinogen, decreased platelets and elevated prothrombin time, occurred in approximately half of patients studied. The clinical significance of these recurrent abnormalities is not known; however, one systematic review of the literature showed that medically significant bleeding following treatment of Crotaline snake envenomation is uncommon, occurring with an estimated frequency of 0.5% [13]. Recurrent coagulation abnormalities were observed only in patients who experienced coagulation abnormalities during their initial hospitalization, although coagulopathy can initially appear at any time before, during or after treatment. Optimal dosing to completely prevent recurrent coagulopathy has not been determined. Because CROFAB has a shorter persistence in the blood than the snake venoms that can leak from depot sites over a prolonged period of time, repeat dosing to prevent or treat such recurrence may be necessary [see Dosage and Administration (2)].

Recurrent coagulopathy may persist for 1 to 2 weeks or more. Patients who experience coagulopathy due to snakebite during hospitalization for initial treatment should be monitored for signs and symptoms of recurrent coagulopathy for up to 1 week or longer at the physician’s discretion. During this period, the physician should carefully assess the need for re-treatment with CROFAB and use of any type of anticoagulant or anti-platelet drug.

Because snake envenomation can cause coagulation abnormalities, the following conditions, which are also associated with coagulation defects, should be considered: cancer, collagen disease, congestive heart failure, diarrhea, elevated temperature, hepatic disorders, hyperthyroidism, poor nutritional state, steatorrhea, vitamin K deficiency.

5.2 Hypersensitivity Reactions

Severe hypersensitivity reactions may occur with CROFAB. In case of acute hypersensitivity reactions, including anaphylaxis and anaphylactoid reactions, discontinue infusion and institute appropriate emergency treatment.

CROFAB contains purified immunoglobulin fragments from the blood of sheep that have been immunized with snake venoms [see Description (11)]. Injection of heterologous animal proteins can cause severe acute and delayed hypersensitivity reactions (late serum reaction or serum sickness) and a possible febrile response to immune complexes formed by animal antibodies and neutralized venom components [11].

Papain is used to cleave antibodies into fragments during the processing of CROFAB, and trace amounts of papain or inactivated papain residues may be present. Patients allergic to papain, chymopapain, other papaya extracts, or the pineapple enzyme bromelain may also have an allergic reaction to CROFAB. Some dust mite allergens and some latex allergens share antigenic structures with papain and patients with these allergies may be allergic to papain [7, 8].

Use the following precautions to manage hypersensitivity reactions:

- Emergency medical care (e.g., epinephrine, intravenous antihistamines and/or albuterol) should be readily available.
- Carefully monitor patients for signs and symptoms of an acute allergic reaction (e.g., urticaria, pruritus, erythema, angioedema, bronchospasm with wheezing or cough, stridor, laryngeal edema, hypotension, tachycardia).
- Follow-up all patients for signs and symptoms of delayed allergic reactions or serum sickness (e.g., rash, fever, myalgia, arthralgia).

Patients who receive a course of treatment with a foreign protein such as CROFAB may become sensitized to it. Therefore, caution should be used when administering a repeat course of treatment with CROFAB for a subsequent envenomation episode.
Skin testing has not been used in clinical trials of CROFAB and is not required.

5.3 Mercury Toxicity

The final product contains up to 30 mcg or approximately 0.03 mg of mercury per vial, which amounts up to 0.6 mg of mercury per dose (based on the maximum dose of 18 vials studied in clinical trials of CROFAB). While there are no definitive data on the toxicity of ethyl mercury, literature suggests that information related to methyl mercury toxicities may be applicable.

6 ADVERSE REACTIONS

Most common adverse reactions (incidence ≥5% of subjects) were urticaria, rash, nausea, pruritus and back pain.

The following clinically significant adverse reactions are described elsewhere in the labeling:

- Hypersensitivity Reactions [see Warnings and Precautions (5.2)]

6.1 Clinical Trials Experience

Because clinical trials are conducted under widely varying conditions, adverse reaction rates observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another drug and may not reflect the rates observed in clinical practice.

The safety of CROFAB was evaluated in 289 patients who received CROFAB for crotalid envenomation. Forty-two patients were from two prospective clinical trials in patients who experienced mild to moderate crotalid envenomation; 247 patients were from a retrospective study in patients who experienced mild, moderate or severe envenomation. There also were safety information extracted from literature review of publications on CROFAB that contained patient exposure data.

Premarketing Prospective Clinical Trials

A total 42 patients received CROFAB for treatment of mild to moderate crotalid envenomation in two clinical studies. The patients were aged 11 to 76 years, and 34 were male and 8 were female. Nineteen patients experienced an adverse reaction for a total of 26 adverse reactions. Adverse reactions involving the skin and appendages (primarily rash, urticaria, and pruritus) were reported in 12 of the 42 patients (see Table 1). One patient discontinued CROFAB therapy due to an allergic reaction.

Of the 19 patients who experienced adverse reactions, 3 patients experienced severe or serious adverse reactions.

- 1 patient who experienced a serious adverse reaction had recurrent coagulopathy due to envenomation, which required re-hospitalization and additional antivenin administration. This patient eventually made a complete recovery.
- 2 patients had severe adverse reactions that consisted of 1 patient who developed severe urticaria following treatment and 1 patient who developed a severe rash and pruritus several days following treatment. Both patients recovered following treatment with antihistamines and prednisone.

†  Allergic reaction consisted of urticaria, dyspnea and wheezing in 1 patient.

Six of 42 patients experienced an adverse reaction associated with an early serum reaction and four experienced an adverse reaction associated with a late serum reaction. Two additional patients were considered to have experienced a late serum reaction by the investigator, although no associated adverse reaction was reported. Serum reactions are defined as reactions associated with CROFAB infusion. They consisted mainly of urticaria and rash, and all patients recovered without sequelae. Table 2 lists the incidence of early and late serum reactions. There were 7 events classified as early serum reactions and 5 events classified as late serum reactions; none was serious.

Postmarketing Retrospective Study

This was a retrospective study of data collected from postmarketing use of CROFAB to compare treatment and outcome characteristics between patients with severe envenomation to those with mild to moderate envenomation. A total of 247 patients received CROFAB for treatment of mild, moderate or severe crotalid envenomation. The patients were aged 1 to 91 years, and 206 were male and 41 were female. Of the 247 patients, 209 were classified as mild/moderate (n=181) or severe (n=28), while 38 patients did not have enough data to calculate an initial severity score.

There were a total of 36 immediate adverse drug reactions reported in 15 patients (6.1%, n = 247).
There were 11 immediate serious adverse events related to CROFAB administration reported in four patients. The events included two episodes each of hypotension and tongue swelling, and one episode each of chest discomfort, angioedema, bronchospasm, wheezing, tracheal edema, dyspnea, and lip swelling.

There were 22 immediate non-serious adverse events related to CROFAB administration reported in 12 patients. The events included four episodes each of rash and pruritus, three episodes of urticaria and one episode each of tachycardia, tachypnea, erythema, swelling, hyperhidrosis, dizziness, headache, musculoskeletal chest pain, chills, feeling cold and nervousness.

Delayed hypersensitivity reactions were reported for two patients. In one patient, symptoms described as hives, itching and epigastric pressure occurred 6 days post-dosing and were not serious. In the second patient, symptoms were not described in the medical records and therefore were not captured in this study.

Recurrent coagulopathy developed in 5 severely envenomated patients and in 6 mild/moderate envenomated patients. In addition, 7 mild/moderate patients experienced delayed-onset coagulopathy. One severely envenomated patient with recurrent coagulopathy experienced medically significant bleeding.

Additional Published Clinical Studies Experience

From a literature review of nine publications on CROFAB that contained patient exposure data, 15 of 313 (4.8%) patients receiving CROFAB experienced acute hypersensitivity reactions. The most common signs and symptoms associated with these reactions were rash (10 patients) and wheezing (3 patients). Most reactions were mild, resolved after antihistamine therapy, and did not require discontinuation of antivenom therapy. No patient developed a life-threatening hypersensitivity reaction, required intubation, suffered lasting ill-effect or died as a result of CROFAB administration.

Follow up data (minimum of six days after treatment) were available in 94 of the 313 patients. Delayed hypersensitivity reactions were reported in 10 cases. The most common signs and symptoms of delayed hypersensitivity were rash (9 patients) and fever (3 patients). Most were mild and treated with antihistamines and steroids.

6.2 Postmarketing Experience

The following additional adverse reactions have been identified during post approval use of CROFAB. Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to product exposure:

- Delayed allergic reaction manifested by fever, pruritus and/or rash
- Delayed or recurrent coagulopathy or thrombocytopenia
- Failure to achieve initial control
- Recurrent swelling refractory to treatment
- Thrombocytopenia refractory to treatment
- Prolonged hospitalization
- Bleeding
- Tremor
- Treatment failure resulting in death

8 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy

Risk Summary

Animal reproduction studies have not been conducted with CROFAB. It is also not known whether CROFAB can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity. CROFAB should be given to a pregnant woman only if clearly needed. In the U.S. general population, the estimated background risk of major birth defects and miscarriage in clinically recognized pregnancies is 2-4% and 15-20%, respectively.

Clinical Considerations

CROFAB contains mercury in the form of ethyl mercury from thimerosal [see Warnings and Precautions (5.3)]. Although there are limited toxicology data on ethyl mercury, high dose and acute exposures to methyl mercury have been associated with neurological and renal toxicities. Developing fetuses and very young children are most susceptible and therefore, at greater risk.

8.2 Lactation
Risk Summary
It is not known whether CROFAB is excreted in human breast milk. Because many drugs are excreted in human milk, caution should be exercised when CROFAB is administered to a nursing woman.

8.4 Pediatric Use
Thirty-two percent (78/247) of patients studied in a post-marketing retrospective study of CROFAB were 16 years of age or younger (median 8.5 years [range 1 to 16 years]). Initial control of envenomation was achieved in 64/72 (89%) of pediatric patients, which was similar to the initial control rate in adults (103/128, 80%). Changes in severity score, recurrence and incidence of adverse reactions were similar between pediatric and adult patients, indicating safety and efficacy in the pediatric population are comparable to that in adults. Limited published clinical experience has not shown that a dosage adjustment for age should be made [14, 15].

CROFAB contains mercury in the form of ethyl mercury from thimerosal [see Warnings and Precautions (5.3)]. Although there are limited toxicology data on ethyl mercury, high dose and acute exposures to methyl mercury have been associated with neurological and renal toxicities. Developing fetuses and very young children are most susceptible and therefore, at greater risk.

8.5 Geriatric Use
Five percent (13/247) of patients studied in a post-marketing retrospective study of CROFAB were over 65 years of age (median 72 years [range 67 to 91 years]). The efficacy and safety of CROFAB in the geriatric population appears comparable to the overall population.

11 DESCRIPTION
CROFAB [Crotalidae Polyvalent Immune Fab (Ovine)] is a sterile, nonpyrogenic, purified, lyophilized preparation of ovine Fab (monovalent) immunoglobulin fragments obtained from the blood of healthy sheep flocks immunized with one of the following North American snake venoms: Crotalus atrox (Western Diamondback rattlesnake), Crotalus adamanteus (Eastern Diamondback rattlesnake), Crotalus scutulatus (Mojave rattlesnake), and Agkistrodon piscivorus (Cottonmouth or Water Moccasin). To obtain the final antivenin product, the four different monospecific antivenins are mixed. Each monospecific antivenin is prepared by fractionating the immunoglobulin from the ovine serum, digesting it with papain, and isolating the venom specific Fab fragments on ion exchange and affinity chromatography columns.

CROFAB is standardized by its ability to neutralize the lethal action of each of the four venom immunogens following intravenous injection in mice. The potency of the product will vary from batch to batch; however, a minimum number of mouse LD$_{50}$ neutralizing units against each of the four venoms is included in every vial of final product, as shown in Table 3.

<table>

</tbody>
</table>

1 One neutralizing unit is determined as the amount of the mixed monospecific Fab proteins necessary to neutralize one LD$_{50}$ of each of the four venoms, where the LD$_{50}$ is the amount of venom that would be lethal in 50% of mice.

2 As of 2008, the potency assay has been optimized for a new strain of mice, which has resulted in changes to the minimum mouse LD$_{50}$ neutralizing units. These changes do not reflect any change in product potency, but only a different biological response of the mouse strain to the venom.

Each vial of CROFAB contains up to 1 gram of total protein and sodium phosphate buffer consisting of dibasic sodium phosphate USP and sodium chloride USP. Thimerosal is used as a preservative in the manufacturing process, and as such, mercury is carried over into the final product at an amount no greater than 30 mcg per vial, which amounts to no more than 0.6 mg of mercury per dose (based on the maximum dose of 18 vials used in clinical studies of CROFAB). The product is intended for intravenous administration after reconstitution with 18 mL of 0.9% Sodium Chloride.
12 CLINICAL PHARMACOLOGY

12.1 Mechanism of Action

CROFAB is a venom-specific Fab fragment of immunoglobulin G (IgG) that works by binding and neutralizing venom toxins, facilitating their redistribution away from target tissues and their elimination from the body.

12.3 Pharmacokinetics

A limited number of samples were collected from three patients in the pharmacokinetic study of CROFAB. Based on these data, estimates of elimination half-life were made. The elimination half-life for total Fab ranged from approximately 12 to 23 hours. These limited pharmacokinetic estimates of half-life are augmented by data obtained with an analogous ovine Fab product produced by BTG International Inc. using a similar production process. In that study, 8 healthy subjects were given 1 mg of intravenous digoxin followed by an approximately equimolar neutralizing dose of 76 mg of digoxin immune Fab (ovine). Total Fab was shown to have a volume of distribution of 0.3 L/kg, a systemic clearance of 32 mL/min (approximately 0.4 mL/min/kg) and an elimination half-life of approximately 15 hours.

13 NONCLINICAL TOXICOLOGY

13.2 Animal Toxicology and/or Pharmacology

CROFAB was effective in neutralizing the venoms of 10 clinically important North American crotalid snakes in a murine lethality model (see Table 4) [1]. In addition, preliminary data from experiments in mice using whole IgG from the sheep immunized for CROFAB production suggest that CROFAB might possess antigenic cross-reactivity against the venoms of some Middle Eastern and North African snakes; however, there are no clinical data available to confirm these findings.

14 CLINICAL STUDIES

The safety and efficacy of CROFAB in crotalid envenomation were evaluated in two premarketing prospective and one postmarketing retrospective studies. The prospective studies evaluated patients suffering from minimal to moderate North American crotalid envenomation. The postmarketing study evaluated patients suffering from mild, moderate or severe envenomation. The definition of minimal, moderate, and severe envenomation in clinical studies of CROFAB is provided in Table 5.
significantly decreased across the patient groups by the 12 hour assessment, 10 out of 11 patients had no change or a decrease in their ES. Ten of 11 patients were also judged to have a clinical response (pre-treatment signs and symptoms of envenomation were arrested or improved after treatment) by the ICA. Two patients demonstrated a need for additional antivenom to stem progressive or recurrent symptoms and signs; one patient received an additional 4 vials of CROFAB, and 10 out of 11 patients had no change or a decrease in their ES. Ten of 11 patients were also judged to have a clinical response (pre-treatment signs and symptoms of envenomation were arrested or improved after treatment) by the ICA. Two patients demonstrated a need for additional antivenom to stem progressive or recurrent symptoms and signs; one patient received an additional 4 vials of CROFAB. No patient in this study experienced an anaphylactic or anaphylactoid response or evidence of an early or late serum reaction as a result of administration of CROFAB.

Based on observations from the first study, the second clinical study compared two different CROFAB dosage schedules. Patients were given an initial intravenous dose of 6 vials of CROFAB with an option to retreat with an additional 6 vials, if needed, to achieve initial control of the envenomation syndrome. Initial control was defined as complete arrest of local manifestations and normalization of coagulation tests and systemic signs. Once initial control was achieved, patients were randomized to receive additional CROFAB either every 6 hours for 18 hours (Scheduled Group) or as needed (PRN Group).

In this study, CROFAB was administered to 31 patients with minimal or moderate crotalid envenomation. All 31 patients enrolled in the study achieved initial control of their envenomation with CROFAB, and 30, 25 and 26 of the 31 patients achieved a clinical response based on the ICA at 1, 6 and 12 hours respectively following initial control. Additionally, the mean ES was significantly decreased across the patient groups by the 12-hour evaluation time point (p=0.05 for the Scheduled Group; p=0.05

                       | Coagulation parameters normal with no clinical evidence of bleeding |
| Moderate              | Swelling, pain, and ecchymosis involving less than a full extremity or, if bite was sustained on the trunk, head or neck, extending less than 50 cm  
                       | Systemic signs and symptoms may be present but not life threatening, including but not limited to nausea, vomiting, oral paresthesia or unusual tastes, mild hypotension (systolic blood pressure >90 mmHg), mild tachycardia (heart rate <150), and tachypnea  
                       | Coagulation parameters may be abnormal, but no clinical evidence of bleeding present (minor hematuria, gum bleeding and nosebleeds are allowed if they are not considered severe in the investigator’s judgment) |
| Severe                | Swelling, pain, and ecchymosis involving more than an entire extremity or threatening the airway  
                       | Systemic signs and symptoms are markedly abnormal, including severe alteration of mental status, severe hypotension, severe tachycardia, tachypnea, or respiratory insufficiency  
                       | Coagulation parameters are abnormal, with serious bleeding or severe threat of bleeding |

Premarketing Prospective Studies

Two premarketing prospectively defined, open label, multi-center trials were conducted in otherwise healthy patients 11 years of age or older who had experienced minimal or moderate North American crotalid envenomation that showed evidence of progression. Progression was defined as the worsening of any evaluation parameter used in the grading of an envenomation: local injury, laboratory abnormality or symptoms and signs attributable to crotalid snake venom poisoning. Both clinical trials excluded patients with Copperhead envenomation.

Efficacy was determined using a Snakebite Severity Score (SSS) [2] (referred to as the efficacy score or ES) and an investigator’s clinical assessment (ICA) of efficacy. The SSS is a tool used to measure the severity of envenomation based on six body categories: local wound (e.g., pain, swelling and ecchymosis), pulmonary, cardiovascular, gastrointestinal, hematological and nervous system effects. A higher score indicates worse symptoms. CROFAB was required to prevent an increase in the ES in order to demonstrate efficacy.

The ICA was based on the investigator’s clinical judgment as to whether the patient had a:

- Clinical response (pre-treatment signs and symptoms of envenomation were arrested or improved after treatment)
- Partial response (signs and symptoms of envenomation worsened, but at a slower rate than expected after treatment)
- Non-response (the patient’s condition was not favorably affected by the treatment)

Safety was assessed during CROFAB infusion by monitoring for early allergic events, such as anaphylaxis and early serum reactions, and late events, such as late serum reactions [see Adverse Reactions (6.1)].

In clinical study 1, 11 patients received an intravenous dose of 4 vials of CROFAB over 60 minutes. An additional 4-vial dose of CROFAB was administered after completion of the first CROFAB infusion, if deemed necessary by the investigator. At the 1-hour assessment, 10 out of 11 patients had no change or a decrease in their ES. Ten of 11 patients were also judged to have a clinical response by the ICA. After initial clinical response, two patients demonstrated a need for additional antivenom to stem progressive or recurrent symptoms and signs; one patient received an additional 4 vials of CROFAB. No patient in this study experienced an anaphylactic or anaphylactoid response or evidence of an early or late serum reaction as a result of administration of CROFAB.

Based on observations from the first study, the second clinical study compared two different CROFAB dosage schedules. Patients were given an initial intravenous dose of 6 vials of CROFAB with an option to retreat with an additional 6 vials, if needed, to achieve initial control of the envenomation syndrome. Initial control was defined as complete arrest of local manifestations and normalization of coagulation tests and systemic signs. Once initial control was achieved, patients were randomized to receive additional CROFAB either every 6 hours for 18 hours (Scheduled Group) or as needed (PRN Group).

In this study, CROFAB was administered to 31 patients with minimal or moderate crotalid envenomation. All 31 patients enrolled in the study achieved initial control of their envenomation with CROFAB, and 30, 25 and 26 of the 31 patients achieved a clinical response based on the ICA at 1, 6 and 12 hours respectively following initial control. Additionally, the mean ES was significantly decreased across the patient groups by the 12-hour evaluation time point (p=0.05 for the Scheduled Group; p=0.05

* No change or a decline in the Efficacy Score was considered an indication of clinical response and a sign of efficacy

** For both the Scheduled and the PRN Groups, differences in the Efficacy Score at the four post-baseline assessment times were statistically decreased from baseline by Friedman’s test (p < 0.001)

It has been noted in published literature accounts of rattlesnake bites that a decrease in platelets can accompany moderately severe envenomation that was not corrected by whole blood transfusions [3]. These reductions in platelet count have been observed to last from several hours to several days following the venomous bite [3, 4, 5]. In clinical study 2, 6 patients had predosing platelet counts below 100,000/mm$^3$ (baseline average of 44,000/mm$^3$). Platelet counts for all 6 patients increased to normal levels (average 209,000/mm$^3$) at 1 hour following initial control dosing with CROFAB (see Figure 1).

Figure 1 Platelet Counts from Baseline to 36 Hours for Patients with Counts <100,000/mm$^3$ at Baseline (Clinical Study 2)

Although the difference in the decrease in ES between the two treatment groups was not significant, the data suggest that Scheduled dosing may provide better control of envenomation symptoms caused by continued leakage of venom from depot sites. Scheduled patients experienced a lower incidence of coagulation abnormalities at follow up compared with PRN patients (see Table 7) and more patients in the PRN Group showed a reduction in platelet count after discharge than in the Scheduled Group (see Figure 2). The need to administer additional CROFAB to patients in the PRN Group after initial control suggests there is continued need of antivenin for adequate treatment.
Postmarketing Retrospective Study

Following marketing approval of CROFAB, a retrospective study was conducted to assess the efficacy of CROFAB in mild, moderate and severe crotalid envenomation. This study was a multi-center, retrospective chart review of medical records of snakebite patients treated with CROFAB that compared treatment and outcomes of severe envenomation with those of mild and moderate envenomation. The primary efficacy variable was severity of envenomation as determined by a 7-point severity score. Patients were classified as having mild, moderate or severe envenomation based on their scores just prior to receiving antivenom. Those subjects with a severity score of 5 or 6 at the start of antivenom therapy were a priori defined as severe envenomations; those with a score of 3 or 4 were defined as moderate envenomations; and those with a score of 1 or 2 were defined as mild
CROFAB® CROTALIDAE POLYVALENT IMMUNE FAB (OVINE)

envenomations (see Table 5). A total of 247 patients of all severities were included in the study. Patients with enough data to determine baseline severity were included in the efficacy evaluation. This comprised a cohort of 209 patients, of whom 28 were classified as severe.

Improvement in severity score was observed in all 28 severely envenomated patients. Improvement was noted for each severe venom effect studied, including limb pain and swelling; cardiovascular, respiratory, gastrointestinal and neurologic effects; and coagulopathy/thrombocytopenia and significant/spontaneous bleeding. The median dose of CROFAB administered to treat these severe venom effects was 9 vials (median of 2 doses). Initial control of envenomation was achieved in 57% (16/28) of severely envenomated patients and 87% (158/181) of mild/moderate envenomated patients. In both groups, failure to achieve initial control was most commonly attributable to persistent coagulopathy and/or thrombocytopenia, which occurred in 1 severe case. All 12 severe patients who did not achieve initial control received only one bolus dose of 4 to 6 vials to try to achieve initial control of envenomation. Of the 23 mild/moderate cases who did not achieve initial control, 19 did not follow recommended dosing for number of doses and vials. Whether initial control could have been achieved with larger initial doses of antivenom cannot be determined from this retrospective study. All patients, whether or not they achieved initial control, experienced significant improvement of venom effects and decreased severity scores after receiving CROFAB. Among patients with severe envenomation who did not achieve initial control, median severity score improved from 5 (range: 5 – 6) before CROFAB administration to 2 (range: 1 – 4) at the last loading dose. No patient in this analysis had a severity score greater than 3 at time of final clinical assessment.

16 HOW SUPPLIED/STORAGE AND HANDLING

How Supplied

CROFAB® is supplied as a carton that contains 2 vials of product (diluent not included) [NDC 50633-110-12]. Each vial of CROFAB contains up to 1 gram of lyophilized total protein and not less than the indicated number of mouse LD50 neutralizing units:
### Snake Species Used for Antivenin Component

### Storage and Handling

- Store vials at 2° to 8°C (36° to 46°F). A temperature excursion for no longer than 7 days within the range of -20° to 25°C (-4° to 77°F) is permitted.
- Do not freeze.
- Use within 4 hours after reconstitution.

### PATIENT COUNSELING INFORMATION

- Advise patients to contact their physician immediately if they experience unusual bruising or bleeding (e.g., nosebleeds, excessive bleeding after brushing teeth, the appearance of blood in stools or urine, excessive menstrual bleeding, petechiae, excessive bruising or persistent oozing from superficial injuries) after hospital discharge. Such bruising or bleeding may occur for up to 1 week or longer following initial treatment.
- Advise patients to contact their physician immediately if they experience any signs and symptoms of delayed allergic reactions or serum sickness (e.g., rash, pruritus, urticaria) after hospital discharge.
